# **Fully connected networks**

In the previous notebook, you implemented a simple two-layer neural network class. However, this class is not modular. If you wanted to change the number of layers, you would need to write a new loss and gradient function. If you wanted to optimize the network with different optimizers, you'd need to write new training functions. If you wanted to incorporate regularizations, you'd have to modify the loss and gradient function.

Instead of having to modify functions each time, for the rest of the class, we'll work in a more modular framework where we define forward and backward layers that calculate losses and gradients respectively. Since the forward and backward layers share intermediate values that are useful for calculating both the loss and the gradient, we'll also have these function return "caches" which store useful intermediate values.

The goal is that through this modular design, we can build different sized neural networks for various applications.

In this HW #3, we'll define the basic architecture, and in HW #4, we'll build on this framework to implement different optimizers and regularizations (like BatchNorm and Dropout).

CS231n has built a solid API for building these modular frameworks and training them, and we will use their very well implemented framework as opposed to "reinventing the wheel." This includes using their Solver, various utility functions, and their layer structure. This also includes nndl.fc\_net, nndl.layers, and nndl.layer\_utils. As in prior assignments, we thank Serena Yeung & Justin Johnson for permission to use code written for the CS 231n class (cs231n.stanford.edu).

### **Modular layers**

This notebook will build modular layers in the following manner. First, there will be a forward pass for a given layer with inputs (x) and return the output of that layer (out) as well as cached variables (cache) that will be used to calculate the gradient in the backward pass.

```
def layer_forward(x, w):
    """ Receive inputs x and weights w """
    # Do some computations ...
    z = # ... some intermediate value
    # Do some more computations ...
    out = # the output

cache = (x, w, z, out) # Values we need to compute gradients
    return out, cache
```

The backward pass will receive upstream derivatives and the cache object, and will return gradients with respect to the inputs and weights, like this:

```
def layer_backward(dout, cache):
    """

    Receive derivative of loss with respect to outputs and cache,
    and compute derivative with respect to inputs.
    """

# Unpack cache values
    x, w, z, out = cache

# Use values in cache to compute derivatives
    dx = # Derivative of loss with respect to x
    dw = # Derivative of loss with respect to w
return dx, dw
```

```

```

# **Linear layers**

In this section, we'll implement the forward and backward pass for the linear layers.

The linear layer forward pass is the function affine\_forward in nndl/layers.py and the backward pass is affine\_backward.

After you have implemented these, test your implementation by running the cell below.

#### Affine layer forward pass

Implement affine forward and then test your code by running the following cell.

```
In [3]: # Test the affine forward function
        num inputs = 2
        input shape = (4, 5, 6)
        output dim = 3
        input size = num_inputs * np.prod(input_shape)
        weight size = output dim * np.prod(input shape)
        x = np.linspace(-0.1, 0.5, num=input size).reshape(num inputs, *input
        shape)
        w = np.linspace(-0.2, 0.3, num=weight size).reshape(np.prod(input shap))
        e), output dim)
        b = np.linspace(-0.3, 0.1, num=output dim)
        out, = affine forward(x, w, b)
        correct out = np.array([[ 1.49834967, 1.70660132, 1.91485297],
                                [ 3.25553199, 3.5141327, 3.77273342]])
        # Compare your output with ours. The error should be around 1e-9.
        print('Testing affine forward function:')
        print('difference: {}'.format(rel error(out, correct out)))
        Testing affine forward function:
```

Testing affine\_forward function: difference: 9.7698500479884e-10

### Affine layer backward pass

Implement affine backward and then test your code by running the following cell.

```
In [4]: # Test the affine backward function
        x = np.random.randn(10, 2, 3)
        w = np.random.randn(6, 5)
        b = np.random.randn(5)
        dout = np.random.randn(10, 5)
        dx num = eval numerical gradient array(lambda x: affine forward(x, w,
        b)[0], x, dout)
        dw num = eval numerical gradient array(lambda w: affine forward(x, w,
        b)[0], w, dout)
        db num = eval numerical gradient array(lambda b: affine forward(x, w,
        b)[0], b, dout)
        _, cache = affine_forward(x, w, b)
        dx, dw, db = affine backward(dout, cache)
        # The error should be around 1e-10
        print('Testing affine backward function:')
        print('dx error: {}'.format(rel error(dx num, dx)))
        print('dw error: {}'.format(rel error(dw num, dw)))
        print('db error: {}'.format(rel_error(db_num, db)))
        Testing affine backward function:
```

Testing affine\_backward functions dx error: 3.678671866962789e-10 dw error: 1.817932234015187e-10 db error: 8.550147283236156e-12

## **Activation layers**

In this section you'll implement the ReLU activation.

### ReLU forward pass

Implement the relu\_forward function in nndl/layers.py and then test your code by running the following cell.

```
In [5]: # Test the relu forward function
       x = np.linspace(-0.5, 0.5, num=12).reshape(3, 4)
       print('x:',x)
       out, = relu forward(x)
       correct out = np.array([[ 0.,
                                      0.,
                                                                   0.,
       ],
                             0., 0.04545455, 0.136
       36364,],
                              [0.22727273, 0.31818182, 0.40909091, 0.5,
       ]])
       # Compare your output with ours. The error should be around 1e-8
       print('Testing relu forward function:')
       print('difference: {}'.format(rel_error(out, correct_out)))
       x: [[-0.5
                       -0.40909091 -0.31818182 -0.22727273
        [-0.13636364 - 0.04545455 0.04545455 0.13636364]
        [ 0.22727273  0.31818182  0.40909091  0.5
                                                     ]]
       Testing relu forward function:
       difference: 4.999999798022158e-08
```

#### **ReLU backward pass**

Implement the relu\_backward function in nndl/layers.py and then test your code by running the following cell.

Testing relu\_backward function: dx error: 3.2756143563870376e-12

```
In [6]: x = np.random.randn(10, 10)
dout = np.random.randn(*x.shape)

dx_num = eval_numerical_gradient_array(lambda x: relu_forward(x)[0], x
, dout)

_, cache = relu_forward(x)
dx = relu_backward(dout, cache)

# The error should be around 1e-12
print('Testing relu_backward function:')
print('dx error: {}'.format(rel_error(dx_num, dx)))
```

### Combining the affine and ReLU layers

Often times, an affine layer will be followed by a ReLU layer. So let's make one that puts them together. Layers that are combined are stored in nndl/layer\_utils.py.

#### **Affine-ReLU layers**

We've implemented affine\_relu\_forward() and affine\_relu\_backward in nndl/layer\_utils.py. Take a look at them to make sure you understand what's going on. Then run the following cell to ensure its implemented correctly.

```
In [7]: from nndl.layer utils import affine relu forward, affine relu backward
        x = np.random.randn(2, 3, 4)
        w = np.random.randn(12, 10)
        b = np.random.randn(10)
        dout = np.random.randn(2, 10)
        out, cache = affine relu forward(x, w, b)
        dx, dw, db = affine relu backward(dout, cache)
        dx num = eval numerical gradient array(lambda x: affine relu forward(x
        , w, b)[0], x, dout)
        dw num = eval numerical gradient array(lambda w: affine relu forward(x
        , w, b)[0], w, dout)
        db num = eval numerical gradient array(lambda b: affine relu forward(x
        , w, b)[0], b, dout)
        print('Testing affine relu forward and affine relu backward:')
        print('dx error: {}'.format(rel error(dx num, dx)))
        print('dw error: {}'.format(rel error(dw num, dw)))
        print('db error: {}'.format(rel error(db num, db)))
        Testing affine_relu_forward and affine_relu_backward:
        dx error: 1.7240391252906472e-10
        dw error: 5.055789349356248e-10
        db error: 1.0329060964068354e-11
```

### **Softmax and SVM losses**

You've already implemented these, so we have written these in layers.py. The following code will ensure they are working correctly.

```
In [8]: num classes, num inputs = 10, 50
        x = 0.001 * np.random.randn(num inputs, num classes)
        y = np.random.randint(num classes, size=num inputs)
        dx num = eval numerical gradient(lambda x: svm_loss(x, y)[0], x, verbo
        se=False)
        loss, dx = svm loss(x, y)
        # Test svm loss function. Loss should be around 9 and dx error should
        be 1e-9
        print('Testing svm loss:')
        print('loss: {}'.format(loss))
        print('dx error: {}'.format(rel error(dx num, dx)))
        dx num = eval numerical gradient(lambda x: softmax loss(x, y)[0], x, v
        erbose=False)
        loss, dx = softmax loss(x, y)
        # Test softmax loss function. Loss should be 2.3 and dx error should b
        e 1e-8
        print('\nTesting softmax loss:')
        print('loss: {}'.format(loss))
        print('dx error: {}'.format(rel error(dx num, dx)))
        Testing svm loss:
        loss: 8.999919837997115
        dx error: 1.4021566006651672e-09
        Testing softmax loss:
        loss: 2.3025774937916625
        dx error: 7.173330792038851e-09
```

# Implementation of a two-layer NN

In nndl/fc\_net.py, implement the class TwoLayerNet which uses the layers you made here. When you have finished, the following cell will test your implementation.

```
In [9]: N, D, H, C = 3, 5, 50, 7
X = np.random.randint(C, size=N)

std = 1e-2
model = TwoLayerNet(input_dim=D, hidden_dims=H, num_classes=C, weight_scale=std)

print('Testing initialization ... ')
W1_std = abs(model.params['W1'].std() - std)
b1 = model.params['b1']
W2_std = abs(model.params['W2'].std() - std)
b2 = model.params['b2']
```

```
assert W1 std < std / 10, 'First layer weights do not seem right'
assert np.all(b1 == 0), 'First layer biases do not seem right'
assert W2 std < std / 10, 'Second layer weights do not seem right'
assert np.all(b2 == 0), 'Second layer biases do not seem right'
print('Testing test-time forward pass ... ')
model.params['W1'] = np.linspace(-0.7, 0.3, num=D*H).reshape(D, H)
model.params['b1'] = np.linspace(-0.1, 0.9, num=H)
model.params['W2'] = np.linspace(-0.3, 0.4, num=H*C).reshape(H, C)
model.params['b2'] = np.linspace(-0.9, 0.1, num=C)
X = np.linspace(-5.5, 4.5, num=N*D).reshape(D, N).T
scores = model.loss(X)
correct scores = np.asarray(
  [[11.53165108, 12.2917344,
                                13.05181771, 13.81190102, 14.5719843

#### **Solver**

We will now use the cs231n Solver class to train these networks. Familiarize yourself with the API in cs231n/solver.py. After you have done so, declare an instance of a TwoLayerNet with 200 units and then train it with the Solver. Choose parameters so that your validation accuracy is at least 50%.

```
model = TwoLayerNet()
In [10]:
       solver = None
       # YOUR CODE HERE:
          Declare an instance of a TwoLayerNet and then train
       #
           it with the Solver. Choose hyperparameters so that your validation
           accuracy is at least 40%. We won't have you optimize this further
           since you did it in the previous notebook.
       # ------ #
       model = TwoLayerNet(hidden dims = 200)
       solver = Solver(model, data, update rule='sgd',optim config={
                    'learning rate': 1e-3,
                        },
                        lr decay=0.95,
                        num_epochs=10, batch_size=100,
                        print every=100)
       solver.train()
       # ------ #
       # END YOUR CODE HERE

## **Multilayer Neural Network**

Now, we implement a multi-layer neural network.

Read through the FullyConnectedNet class in the file nndl/fc\_net.py.

Implement the initialization, the forward pass, and the backward pass. There will be lines for batchnorm and dropout layers and caches; ignore these all for now. That'll be in assignment #4.

```
In [12]: N, D, H1, H2, C = 2, 15, 20, 30, 10
         X = np.random.randn(N, D)
         y = np.random.randint(C, size=(N,))
         for reg in [0, 3.14]:
           print('Running check with reg = {}'.format(reg))
           model = FullyConnectedNet([H1, H2], input_dim=D, num_classes=C,
                                     reg=reg, weight scale=5e-2, dtype=np.float
         64)
           loss, grads = model.loss(X, y)
           print('Initial loss: {}'.format(loss))
           for name in sorted(grads):
